

Designation: E3344 – 23

Standard Guide for Developing Representative Sediment Background Concentrations at Sediment Sites—Selection of Background Reference Areas¹

This standard is issued under the fixed designation E3344; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This guide focuses on the selection of sediment background reference areas from aquatic environments for the purpose of developing representative sediment background concentrations. These concentrations are typically used in contaminated sediment corrective actions performed under various regulatory programs, including the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). Although many of the references cited in this guide are CERCLA-oriented, the guide is applicable to remedial actions performed under local, state, tribal, federal, and international cleanup programs. However, this guide does not describe the requirements for each jurisdiction.

1.1.1 The sediment background reference areas chosen using this guide will need to be approved by the regulatory agency having jurisdiction (or they should take no exception to the areas chosen), especially if the representative background sediment concentrations will potentially be used to develop sediment remedial criteria.

1.2 This guide provides a framework to select appropriate sediment background reference areas for the collection of sediment data in the development of representative sediment background concentrations. It is intended to inform, complement, and support, but not supersede, local, state, tribal, federal, or international guidelines.

1.2.1 This guide is designed to apply to contaminated sediment sites where sediment data have been collected and are readily available. Additionally, it assumes that risk assessments have been performed, so that the potential contaminants of concern (PCOCs) that exceed risk-based thresholds have been identified. This guide can be applied at multiple points within the project life cycle (such as site assessment and remedial design).

¹ This guide is under the jurisdiction of ASTM Committee E50 on Environmental Assessment, Risk Management and Corrective Action and is the direct responsibility of Subcommittee E50.04 on Corrective Action.

Current edition approved Sept. 1, 2023. Published November 2023. Originally approved in 2022. Last previous edition approved in 2022 as E3344–22. DOI: 10.1520/E3344–23

1.2.2 Furthermore, this guide presumes that the identified risk-based thresholds are low enough to pose corrective action implementation challenges or that the sediment site is subject to recontamination from ongoing anthropogenic or natural sources (or both) that are not controlled. In either case, representative sediment background concentrations are useful for determining the extent of corrective remedial actions (when used as remedial goals), evaluating risks posed by representative background concentrations, and establishing appropriate post-remedial monitoring plans.

1.2.3 A case study for selecting a background reference area using a tiered decision analysis approach is presented in [Appendix X1](#). It compares various characteristics of a hypothetical sediment site associated with a former upland manufactured gas plant (MGP) facility to three candidate background reference areas and identifies the background reference area that best satisfies the decision analysis objectives.

1.3 Methodologies used to develop representative background concentrations at contaminated sediment sites are not discussed in this guide—refer to Guide [E3242](#) for a discussion of these methodologies.

1.4 *Related ASTM Standards*—This guide is related to Guide [E3382](#), which provides the overarching framework for the development of representative background concentrations at contaminated sediment sites, including Conceptual Site Model (CSM) considerations. This guide is also related to Guide [E3242](#), which provides a detailed framework for developing representative sediment background concentrations, including statistical and geochemical considerations as well as background threshold values. This guide is also related to Guide [E3164](#), which addresses corrective action monitoring before, during, and after sediment remediation activities, as well as Guide [E3163](#), which concerns sediment sampling and analytical techniques used during sediment corrective action projects. Guide [D4823](#), which concerns sediment core sampling, is also related to this guide.

1.4.1 Specifically, this guide is intended to be used under the overarching framework of Guide [E3382](#), in conjunction with the detailed framework to develop representative background values outlined in Guide [E3242](#), to help ensure appropriate

background reference areas are chosen for use in representative background concentration development.

1.5 *Units*—The values stated in SI units are to be regarded as the standard. No other units of measurement are included in this guide.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety, health, and environmental practices and determine the applicability of regulatory limitations prior to use.*

1.7 *This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.*

3. Terminology

3.1 Definitions:

3.1.1 *background (aka “reference”), adj*—a term applied to substances, conditions, or locations that are similar to those found at a sediment site but not influenced by current or historical releases or activities from the sediment site; these are usually a combination of naturally occurring (consistently present in the environment but not influenced by human activity) and anthropogenic (influenced by human activity but not related to specific current or historical releases or activities at the sediment site) components. **E3382**

3.1.2 *background reference areas, n*—sediment areas that have similar physical, chemical, geological, biological, and

land-use characteristics as the site being investigated, but are not affected by site-related releases and/or activities. **E3242**

3.1.3 *candidate background data set, n*—a raw (that is, unprocessed) background data set obtained either by the collection of data from a background reference area(s), or by the extraction of background data from the sediment site data set, or a combination of both. **E3382**

3.1.3.1 *Discussion*—The candidate background data set must first be evaluated using the steps described in Guide **E3242** and Section 5 to obtain a representative background data set, which can then be used to develop representative background concentrations for the sediment site.

3.1.4 *cleanup level, n*—the prescribed average or point sediment concentration of a chemical that shall not be exceeded at the remediated site. **E3242**

3.1.5 *contaminant of concern (COC), n*—substances identified as posing a risk based on a tiered risk assessment and that may warrant corrective action. **E3382**

3.1.5.1 *Discussion*—Typically, all PCOCs identified for a sediment site are evaluated in the risk assessment process. PCOCs that have sediment concentrations greater than risk-based thresholds identified in the risk assessment process are defined as COCs. Thus, the COCs identified for a sediment site are a subset of the PCOCs identified for that site.

3.1.6 *conceptual site model (CSM), n*—the integrated representation of the physical and environmental context, the complete and potentially complete exposure pathways and the potential fate and transport of potential contaminants of concern at a site. **E3242**

3.1.6.1 *Discussion*—The CSM should include both the current understanding of the site and an understanding of the potential future conditions and uses for the site. It provides a method to conduct the exposure pathway evaluation, inventory the exposure pathways evaluated, and determine the status of the exposure pathways as incomplete, potentially complete, or complete.

3.1.7 *population, n*—in statistics, a comprehensive set of values consisting of all possible observations or measurements of a certain phenomenon from which a sample is to be drawn. **E3242**

3.1.8 *potential contaminant of concern (PCOC), n*—a contaminant whose sediment concentrations at the site may exceed applicable screening levels; this includes chemicals of potential environmental concern (COPECs) and chemicals of potential concern (COPCs). **E3242**

3.1.9 *representative background data set, n*—a background data set obtained by evaluating candidate background data using the steps described in Guide **E3242**. **E3382**

3.1.9.1 *Discussion*—The evaluation determines if there are any data points in the candidate background data set that are not representative of sediment site background conditions. These data points are then removed from the candidate background data set (using technically justifiable rationale) to obtain a representative background data set, which is then used to develop representative background concentrations for the sediment site using methodologies described in Guide **E3242**.
